

METHOD FOR FABRICATING A METALLIC OXIDE OF
HIGH DIELECTRIC CONSTANT, METALLIC OXIDE OF
HIGH DIELECTRIC CONSTANT, GATE INSULATING FILM
AND SEMICONDUCTOR ELEMENT

BACKGROUND OF THE INVENTION

Field of the Invention

[0001] This invention relates to a method for fabricating a metallic oxide of high dielectric constant, a metallic oxide of high dielectric constant, a gate
5 insulating film and a semiconductor element.

Description of the related art

[0002] Conventionally, as a gate insulating film of a semiconductor element such as a Si MOSFET, in view of thermal stability and interface characteristic, a Si oxide film has been employed all these years. With the development of
10 performance and function of a semiconductor element, in contrast, the Si oxide film is intended to be thinned. However, it is considered that the thinning of the Si oxide film reaches the limit, so that attention is paid to an insulating film of high dielectric constant substituted for the Si oxide film as the insulating film of high dielectric constant.

15 [0003] In the use of the insulating film of high dielectric constant as the gate insulating film, such various properties are required as high dielectric constant, low leak current, low defect density and flat interface between the Si substrate and the insulating film without any interface layer.

[0004] A conventionally developed insulating film of high dielectric constant
20 has only a polycrystalline structure, so that the large leak current is flowed through the insulating film because the grain boundaries of the insulating film serve as leak current paths. As a result, the conventional insulating film of high dielectric constant can not be employed as the gate insulating film. Also, in the fabrication of the insulating film of high dielectric constant, an interface layer of
25 low dielectric constant and large surface roughness is formed though the reaction between the insulating film deposited and the Si substrate, so that the operating performance of the intended Si MOSFET and the like containing the insulating film of high dielectric constant is deteriorated.

SUMMARY OF THE INVENTION

[0005] It is an object of the present invention to provide a new metallic oxide film of high dielectric constant which has a small amount of defects such as crystal grains to inhibit the leak current sufficiently and thus, is preferably employed as a gate insulating film or the like of a semiconductor element.

[0006] For achieving the above object, this invention relates to a method for fabricating a metallic oxide film of high dielectric constant, comprising the steps of:

10 epitaxially growing a given metallic oxide film on a substrate, and thermally treating the substrate and the metallic oxide film to mix constituent elements of the substrate with constituent metallic oxide elements of the metallic oxide film and to form the metallic oxide film of high dielectric constant on the substrate.

[0007] According to the present invention, the intended metallic oxide film of high dielectric constant can be fabricated through the two fabricating steps of epitaxially growing a metallic oxide film and thermally treating a substrate and the metallic oxide film. In the thermal treatment, the constituent elements of the substrate and the constituent metallic oxide elements of the metallic oxide film are mixed, so that the intended metallic oxide film can be formed in minute polycrystal or amorphous.

[0008] Therefore, the intended metallic oxide film can have sufficient high dielectric constant, and the amount of defect such as crystal grain of the intended metallic oxide film can be reduced sufficiently. As a result, if a Si substrate is employed as the above-mentioned substrate and the insulating film of high dielectric constant is employed as the gate insulating film to fabricate a semiconductor element such as a Si MOSFET, the leak current of the semiconductor element can be reduced sufficiently.

[0009] In the present invention, since the above-mentioned epitaxial growth and thermal treatment are performed under equilibrium state, the metallic oxide film of high dielectric constant can be fabricated under stable state in energy. Therefore, if the metallic oxide film is employed as the gate insulating film and the resultant assembly containing the gate insulating film is processed to fabricate a semiconductor element such as a Si MOSFET, the metallic oxide film

can not suffer from the thermal treatment and the like in the process. As a result, various properties such as crystal structure of the metallic oxide film can be maintained through the process, so that the semiconductor element can be fabricated as designed initially.

5 [0010] Herein, in the metallic oxide film of high dielectric constant of the present invention, the wording "high dielectric constant" is not restricted, but for example, means a relative dielectric constant of 20 or more.

Details, other features and advantages of the present invention will be described below.

10 BRIEF DESCRIPTION OF THE DRAWINGS

For better understanding of the present invention, reference is made to the attached drawings, wherein

Fig. 1 is an explanatory view of a fabricating method of metallic oxide film with high dielectric constant according to the present invention,

15 Fig. 2 is another explanatory view of a fabricating method of metallic oxide film with high dielectric constant according to the present invention, and

Fig. 3 a high resolution TEM photograph of an amorphous Pr_2O_3 film obtained by the fabricating method of the present invention.

[0011]

20 DESCRIPTION OF THE PREFERRED EMBODIMENTS

This invention will be described in detail hereinafter.

Figs. 1 and 2 are explanatory views of a fabricating method of metallic oxide film with high dielectric constant according to the present invention. In the present invention, first of all, as illustrated in Fig. 1, a metallic oxide film 12 is epitaxially grown on a substrate 11 by means of normal film-forming technique. The metallic oxide film 12 is a raw material for an intended metallic oxide film of high dielectric constant to be formed later, so contains constituent elements of the intended metallic oxide film. The metallic oxide is preferably made of high dielectric constant material.

30 [0012] In the use of the intended metallic oxide film as a gate insulating film of a MOSFET and the like, the substrate 11 is constructed of a Si-containing substrate. In the use of a Si substrate, some impurities may be contained in the Si substrate, and an additional thermally oxide film is formed on the Si substrate

to fabricated a multilayered base substrate.

[0013] In the use of the Si-containing substrate as the substrate 11, the metallic oxide film 12 is preferably made of at least one selected from the group consisting of Pr_2O_3 , SrTiO_3 , CeO_2 , ZrO_2 and Y_2O_3 . In this case, the metallic oxide film 12
5 can be epitaxially grown easily on the Si-containing substrate, and the dielectric constant of the metallic oxide film 12 can be developed. In addition, the constituent metallic oxide elements of the metallic oxide film 12 can be easily mixed with the constituent elements, that is, Si elements of the Si-containing substrate so that the intended metallic oxide film of high dielectric constant can
10 be easily fabricated.

[0014] Herein, in the epitaxial growth of the metallic oxide film 12 on the substrate 11, if vacuum deposition, sputtering or CVD is employed, the epitaxial growth can be performed by controlling various conditions such as the temperature of the substrate 11. In substitution for the vacuum deposition and the like,
15 liquid epitaxy technique may be employed.

[0015] Then, the substrate 11 and the metallic oxide 12 are thermally treated to mix the constituent elements of the substrate 11 with the constituent metallic oxide elements of the metallic oxide film 12 and to form the intended metallic oxide film 13 of high dielectric constant on the substrate 11.

[0016] The thermal treatment is required to be performed under the expectating condition of mixing. Concretely, the thermal treatment may be preferably performed within a temperature range of 900-1000°C. In this case, the mixing of the constituent elements can be easily performed.

[0017] In addition, the thermal treatment may be preferably performed under
25 non-oxidizing atmosphere. In this case, the formation of an interface layer between the substrate 11 and the metallic oxide film 13 of high dielectric constant can be inhibited, and the surface roughness of the metallic oxide film 13 can be developed. Therefore, various properties such as high dielectric constant of the metallic oxide film 13 can be maintained even though the metallic oxide
30 film 13 is thinned sufficiently, and thus, the metallic oxide film 13 can be employed as a gate insulating film and the like of a semiconductor element such as a MOSFET.

[0018] As the non-oxidizing atmosphere can be exemplified nitrogen

atmosphere, inert gas atmosphere and depressurized atmosphere. In view of simplicity of a thermal treatment apparatus and low cost, the nitrogen atmosphere can be preferably employed.

5 [0019] In the use of the nitrogen atmosphere, the thermal treatment may be performed under atmospheric pressure. In this case, therefore, additional pressurizing operation and depressurizing operation are not required, so that the thermal treatment apparatus and the fabricating process can be simplified.

10 [0020] If the thermal treatment is performed under the above-mentioned preferable temperature range, the heating rate is increased as short period of time as possible so as to enhance the mixing of the constituent elements of the substrate 11 and the metallic oxide film 12 and not to inhibit the formation of an intermediate compound. Concretely, the heating rate is preferably set within 50-100°C/sec.

15 [0021] The metallic oxide film 13 of high dielectric constant is formed in amorphous or polycrystal with minute crystal grains through the mixing of the constituent elements of the substrate 11 and the metallic oxide film 12. As a result, the defects such as grain boundaries and the like can be reduced, and thus, leak current due to the defects can be inhibited effectively. Preferably, the metallic oxide film 13 is rendered amorphous.

20 [0022] As mentioned above, the metallic oxide film 13 can be employed as a gate insulating film of a semiconductor element such as a MOSFET, and the multilayered structure constructed of the metallic oxide film 13 and the substrate 11 can be employed as a gate insulating film structure if the substrate 11 is made of the Si-containing substrate.

25 [0023] In this embodiment, as illustrated in Figs. 1 and 2, since the mixing of the constituent elements is performed over the thickness of the metallic oxide film 12, the metallic oxide film 12 is diminished and converted into the metallic oxide film 13 of high dielectric constant. If the mixing of the constituent elements is stopped on the way of the thickness of the metallic oxide film 12, the
30 metallic oxide film 12 remains partially on the metallic oxide film 13 of high dielectric constant. In the latter case, therefore, the remaining metallic oxide film 12 is removed by means of etching after the formation of the metallic oxide film 13.

[0024]

Example:

(Example)

A Si substrate was prepared, and a Pr_2O_3 film was epitaxially grown
5 in a thickness of 8nm on the Si substrate by means of electron beam deposition.
In the epitaxial growth, the Si substrate was heated at 500°C . Then, the Si
substrate and the P_2O_3 film were thermally treated at 1000°C for 30 seconds
under nitrogen atmosphere and atmospheric pressure to mix the Si elements of
the Si substrate into the P_2O_3 film. Herein, the Si substrate and the P_2O_3 film
10 were heated at 1000°C for 15 seconds.

[0025] Fig. 3 is a high resolution TEM photograph relating to the cross
section of the multilayered structure constructed of the Si substrate and the P_2O_3
film after the thermal treatment. As is apparent from Fig. 3, it was turned out
that the P_2O_3 film was amorphous through the mixing of the constituent elements.
15 It is also turned out that no interface layer is formed between the Si substrate and
the amorphous P_2O_3 film. The specific conductive capacity of the P_2O_3 film
was 20.

[0026] Then, a Pt electrode was formed on the amorphous Pr_2O_3 film to
measure the leak current density. At the measurement, it was turned out that the
20 leak current density was $3.6 \times 10^{-9} \text{ A/cm}^2$. Therefore, the amorphous Pr_2O_3 film
can be preferably employed as a gate insulating film of a MOSFET and the like.

[0027] Although the present invention was described in detail with reference
to the above examples, this invention is not limited to the above disclosure and
every kind of variation and modification may be made without departing from
25 the scope of the present invention.

[0028] As mentioned above, according to the present invention can be
provided a new metallic oxide film of high dielectric constant which has small
amount of defects such as crystal grains to inhibit the leak current sufficiently
and thus, preferably is employed as a gate insulating film or the like of a
30 semiconductor element.
